Frogeye Leaf Spot & Black Rot of Apple - Plant Pathology A list of the top 10 bacterial and fungal fruit tree diseases in the Pacific North. The main symptom is a sunken, dark canker on the trunk and main scaffold branches. The bull's eye rot phase of the disease appears as brown circular spots on the leaves, which eventually turn black and sometimes give off a foul odor. Canker and stem dieback diseases are most common on trees and shrubs under stress. Anthracnose of shade trees - Apple scab - Black knot of ornamental cherry and plum - Brown rot - Cytospora Canker - Gummosis - Bacterial canker - Poor fruiting.

Question: The leaves of my tree have developed greenish-black spots and blotches, and the tree seems to be suffering from some kind of disease. What could be the problem, and how can I address it?

Answer: The symptoms you described suggest that your tree may be suffering from a disease. The greenish-black spots and blotches are common signs of fungal infections, which can be caused by various pathogens such as Cytospora Canker. To address the issue, you should first identify the specific type of fungal infection affecting your tree. This can be done by observing the symptoms and consulting with a local horticulturist or extension service. Once the diagnosis is confirmed, appropriate treatment options can be pursued, which may include applying fungicides, pruning affected branches, or even removing the tree if the problem is severe and widespread.
